I have this fine-tuned model of wand capture here. Not fine-tuned model is not obtained, talked to Professor Dinuka.

Question, reflection:

The baseline model achieved 24.1% accuracy on my digit dataset. Many digits were classified incorrectly, and some classes had very low precision and recall. The confusion matrix showed that the model often confused different digits.

After fine-tuning with my digit data, the model achieved 100% accuracy. All digits were classified correctly, and the confusion matrix showed no misclassifications.

From this result, we could see the fine-tuning helped the model adapt to my handwriting style.

The pretrained model provided a good starting point, but additional training on my data greatly improved its performance.
